Wiki Page Names

Wiki page names commonly use the <u>CamelCase</u> convention. Within wiki text, any word in <u>CamelCase</u> automatically becomes a hyperlink to the wiki page with that name.

<u>CamelCase</u> page names follow these rules:

- 1. The name must consist of **alphabetic characters only**; no digits, spaces, punctuation or underscores are allowed.
- 2. A name must have at least two capital letters.
- 3. The first character must be capitalized.
- 4. Every capital letter must be followed by one or more lower-case letters.
- 5. The use of slash (/) is permitted in page names, where it typically represents a hierarchy.

If you want to create a wiki page that does not follow <u>CamelCase</u> rules. you can use the following syntax:

```
* [wiki:Wiki_page], [wiki:ISO9000],
  and with a label: [wiki:ISO9000 ISO 9000 standard]

* [wiki:"Space Matters"]
  and with a label: [wiki:"Space Matters" all about white space]

* or simply: ["WikiPageName"]s

* even better, the [[WikiCreole link style]]
  and with a label: [[WikiCreole link style|WikiCreole style links]]
```

This will be rendered as:

- Wiki page?, ISO9000?, and with a label: ISO 9000 standard?
- Space Matters? (that page name embeds space characters) and with a label: all about white space?
- or simply: WikiPageName?s
- even better, the WikiCreole link style? and with a label: WikiCreole style links?

It is possible to link to a specific *version* of a Wiki page as you would do for a specific version of a file, for example: WikiStart@1.

You can prevent a CamelCase name from being interpreted as a <u>link</u> by quoting it with an exclamation mark: !CamelCase. See <u>TracLinks#EscapingLinks</u>.

As in the example above, you can append an anchor to a Wiki page name to link to a specific section within that page. The anchor can be seen by hovering the mouse over a section heading, then clicking on the ¶ sign that appears at its end. The anchor is usually generated automatically, but it is also possible to specify it explicitly: see WikiFormatting#using-explicit-id-in-heading.

There are a few options that govern the rendering of <u>WikiPageNames</u>:

- <u>CamelCase</u> linking to missing pages can be disabled with the <code>ignore_missing_pages</code> ?option. Linking to missing pages is enabled by default.
- The split_page_names option, when enabled, will split <u>CamelCase</u> words when rendering a link. For example, <u>WikiStart</u> will be rendered as <u>WikiStart</u>.
